- We continuously develop new and innovative products.

It is well known that **nitrosamines and nitramines** can be dangerous to human health, animals and plant lives. There are several technologies which release them into the environment.

Nitrosamines are a class of chemical compounds that have received much attention since 1956, when two British scientists, John Barnes and Peter Magee, reported that dimethylnitrosamine produced liver tumors in rats. Nitrosamines are formed by reactions of nitrites and secondary amines (e.g. in proteins) under acidic conditions like gastric milieus. Human beings ingest nitrites from food, esp. fried or grilled meat and vegetables. Disposal of tobacco products also causes a high intake of nitrosamines (mainly N-Nitrosonornicotin).

CO₂ capture causes a huge interest in these days. Solvents used for CO₂ capture are often a mixture of several amines according to the latest developments in this field. These amine compositions are not always known in detail. However, it is known that the amine blends for CO₂ capture are recycled, but as a side reaction/effect a certain percentage of the amines are either degraded or emitted to air. The released amines are often unstable on air, and degrade to toxic substances like nitrosamines and nitramines.
