

Antibiotics

BMF 92 - Antibiotics

Antibiotics

Antibiotics are medicines used to treat infections caused by bacteria. People at a high risk may also be given antibiotics to prevent bacterial infections, known as antibiotic prophylaxis. Antibiotics work by killing bacteria i.e. by destroying the cell wall (bactericidal), or preventing them from reproducing and spreading (bacteriostatic). Mild bacterial infections usually get better on their own without using antibiotics. Instead antibiotics should be reserved to treat bacterial infections that are unlikely to resolve on their own, may have a prolonged duration, or lead to serious complications if left untreated. They are also prescribed when an infection may pose a risk to others. When prescribed, antibiotics are effective in easing symptoms and speeding up recovery. In some instances they are lifesaving! Antibiotics don't work against viral infections such as colds and flu.

Antibiotics in the food chain

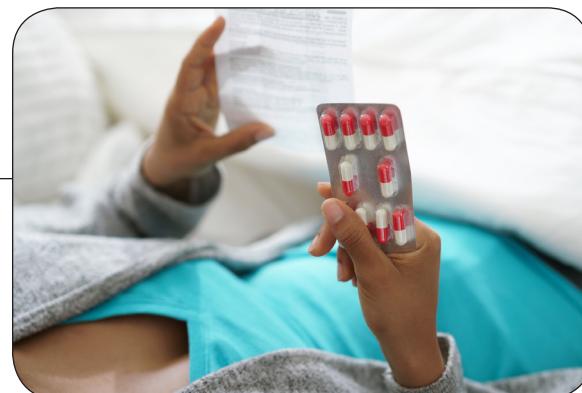

As in humans, antibiotics are used in the prevention and treatment of animal diseases. They are also used to enhance growth performance and feed efficiency, to synchronize or

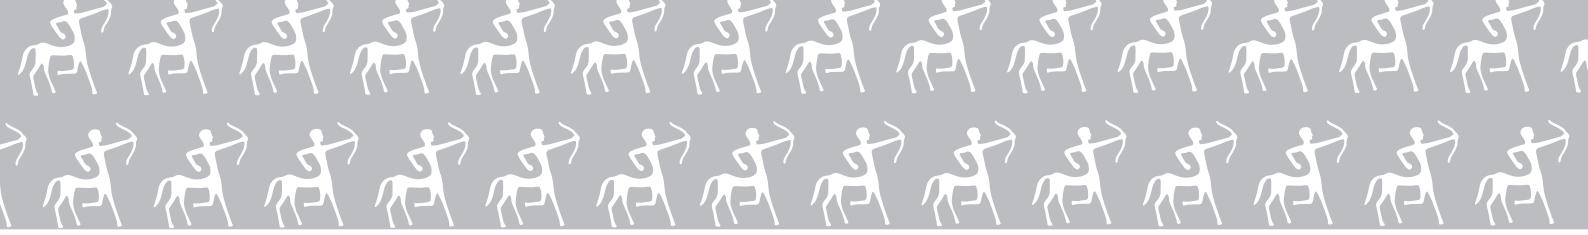

control the reproductive cycle and improve breeding performance. Antibiotics can inadvertently end up in the food chain and be harmful to those consuming them. They can pose a direct threat from toxicity following consumption. Indirectly, low level exposure can alter microflora, cause disease and the possible development of resistant strains, which can cause antibiotic therapy to fail. To safeguard human exposure, and to prevent deposition of residues in meat, milk and eggs destined for the food chain, a withholding period must be observed after treatment to ensure residues are negligible or reach safe concentration. Heavy responsibility is placed on the veterinarian and livestock producer to observe the withdrawal period. WHO and FAO establish tolerances for drugs, pesticide or other chemical in the tissues of food producing animals.

Administration

Antibiotics can be administered in several ways:

- **Oral:** tablets and capsules (most commonly) or a liquid
- **Topical:** creams, lotions, sprays or drops
- **Injection:** intravenous infusion or intramuscular

BMF 92 - Antibiotics

Side effects

The most common side effects include:

- Nausea and vomiting
- Bloating and indigestion
- Diarrhoea
- Fungal infections e.g. thrush due to disruption to healthy bacteria

Types of antibiotics

There are numerous different types of antibiotics, but most can be broadly classified into six groups based on their mechanism of action, chemical structure, or spectrum of activity:

1. Penicillins (e.g. penicillin and amoxicillin)
2. Cephalosporins (e.g. cephalexin)
3. Aminoglycosides (e.g. gentamicin and tobramycin)
4. Tetracyclines (e.g. tetracycline and doxycycline)
5. Macrolides (e.g. erythromycin and clarithromycin)
6. Fluoroquinolones (e.g. ciprofloxacin and levofloxacin)

Broad-spectrum antibiotics can treat infections caused by a wide range of different bacteria. Conversely, narrow-spectrum antibiotics only works against specific bacteria.

Antibiotic resistance

The overuse and misuse of antibiotics in recent years has led to a reduction in their efficiency and the emergence of "superbugs". These are strains of bacteria that have developed resistance to antibiotics. Some multi-resistant bacteria are resistant to several antibiotics at the same time. A resistant bacteria cannot be fully inhibited or killed by an antibiotic, even though the antibiotic may have worked effectively before the resistance occurred. The most common contributors to antibiotic resistance are using antibiotics when you don't really need them and failing to complete a course.

Examples of resistant bacteria include:

- Methicillin-resistant Staphylococcus aureus (MRSA)
- Clostridium difficile (C. diff)
- Multi-drug-resistant tuberculosis (MDR-TB)
- Carbapenemase-producing Enterobacteriaceae (CPE)
